Dated $\qquad$ April 7,1988

#### Abstract

This study examined the effects of verbal suggestion and music listening on mood changes of college students. The 135 volunteers were randomly assigned to one of three conditions (Condition $1 /$ somber depiction with music, Condition $2 /$ pleasant depiction with music, or Condition $3 /$ music only). The Profile of Mood States was administered before and after each condition. Significant differences ( $p<.05$ ) were found between pre and posttest scores within the groups; however, no significant differences were found among the groups for these same measures.

A music questionnaire was administered following the posttest which examined the subjects' preference for the music played, the frequency of experiencing images while listening to music, and their opinion concerning whether the depiction complemented the music. Implications of the results are discussed, and suggestions for future research are given.

## Acknowledgements

There are many people who have assisted and been encouraging throughout this study. My thesis committee, Dr. Gary Howells and Ms. Audree $0^{\prime}$ Connell provided insightful questions. Dr. David Wolfe gave much time and energy supporting this project. He has been an excellent model, representing high academic standards, patience, and having a genuine interest in his students and colleagues. His support was invaluable.

Gratitude is extended to Dr. Roy Childs for his assistance in the comprehension of the statistics. My friends Hope Young and Margene Mastin were there to assist and provide inspiration.

I would also like to express my love and appreciation to my supportive family: my mother, Judith; my father, Robert; and my brother, Eric. To my mom, I am extremely grateful for her typing the raw data. Her enthusiasm, sensitivity and humor have been a motivating force throughout this study, providing support that was priceless.

Music constantly touches our lives. We hear it while we are shopping, in business offices, and in the radio and television advertisements we are exposed to daily. We even turn to music for energy and reflection. Music does seem to affect our mood and the way we feel. Researchers have studied the effects of music and mood interacting with each other, and these studies have manipulated and examined relationships between mood and specific behaviors.

Wessman and Ricks (1966) explained a mood as an emotional or affective response that varied in its lergth, yet was not a permanent condition. A descriptive definition is found in a study by Eagle (1971). He states that "mood is a relatively transient state... which can be cognized by individuals and designated with words" (p.17). Non-Music Studies and Mood Responses

Mood has been examined in respect to its influence on helping behaviors (Carlson \& Miller, 1987; Ridgeway \& Waters, 1987). Negative moods are found to stifle curiosity in college undergraduates (Rodrigue, Olson \& Markely, 1987) and inhibit their ability to recall and process information (Leight \& Ellis, 1981). Physical performance is enhanced when positive moods are present (Kavanagh \& Hausfeld, 1986). Muzekari, Knudsen and Evans (1986), studied psychiatric patients who were shown photographs paired with statements.

For example, the subjects viewed a photograph with a sad face and under the picture was the word excited. Each subject was to express whether the picture was congruent (picture and word the same) or incongruent (picture and word different). Perceptions of emotions were correctly identified when the subjects were shown the photographs that were congruent.

## Music Studies and Mood Responses

Radocy and Boyle (1979) reviewed studies related to music and mood dating from 1927-1960. Each study focused on a different variable, such as listening to pop, folk, and classical music, and on the influence of rhythm, melody, harmony, timbre, pitch, and tone quality on mood states.

Zalanowski, Stratton \& Campos (1987), found that mood changes occur in subjects who were exposed to music alone and subjects who were exposed to pictures and music. Henderson (1983), who studied hospitalized adolescents, found that a planned sequence of music therapy activities can influence mood. Music also enhanced their ability to express their emotions and become cognizant of their moods.

Soothing music inspired helpfulness immediately following an experiment (Fried \& Berkowitz, 1979). In this study, stimulating and aversive pieces of music were used. Stimulating and soothing music produced positive moods, while aversive music encouraged negative moods.

Pignatiello, Camp, and Raser (1986) took the Velten technique (1968), a procedure used to induce mood states of
verbal college students, and substituted verbal suggestion with music, thereby creating a procedure appropriate for verbal and non-verbal individuals. Inducing mood with music will allow future researchers to study a mood with various populations, i.e., testing individuals who speak a different language.

Musical excerpts matched to a person's existing mood may change the direction of that mood in a step-wise fashion. The "Iso" principle, matching a person's actual mood to the music, grasps the subject:s mood, holds it, and permits the mood to alter. Shatin (1970) states that when the music and mood are not matched, the subject will reject the music entirely-"a restless mood will not respond to tranquil music or bored to stimulated" (p. 81).

Live and recorded music were used in studies by Bailey, (1983) and Wheeler (1985). Those who listened to live music reported significantly less tension-anxiety, more vigor and changes in their mood than did subjects who listened to taped music (Bailey). Contrasting results in the Wheeler (1985) study indicated that a person's mood state is determined prior to the music, and the music is not influential in changing that mood. The mode of presentation (live or recorded) did not significantly influence the development of a person's mood, nor did the order of test presentation, as discovered by Eagle (1971).

Influential Elements of Music on Mood Responses
Claims have been made concerning various specific
elements of music, such as major and minor modes, rhythm, harmonies, and tempi, and their effect on mood.

Characteristics of the major modes seem to erhance feelings of happiness, gracefulness, and joy. The minor modes reflect sadness, sentiment and grief. Flowing rhythms aid in promoting gracefulness, happiness, and tenderness, contrasting with vigorous firm rhythms. Dissonant harmonies evoke excitement and lean toward sadness while consorant harmonies promote lyrical and graceful phrasing (Hevner, 1936). Slow tempi typically consisting of 63-80 beats per minute, evoke sad, sentimental responses. Fast tempi, ranging from 102-150 beats per minute, are energetic (Ludin, 1985).

The styles of music used in the above studies are as unique as each individual project. Classical music (Downey \& Knapp, 1927; Eagle, 1971; Fried \& Berkowitz, 1979;

Pignatiello, Camp \& Raser, 1986; Riggs, 1937; Shatin, 1970; Wheeler, 1985; Zalanowski, Stratton \& Campos, 1987), jazz music (Fried \& Berkowitz, 1979; Pignatiello, Camp \& Raser, 1986) and popular music (Bailey, 1983; Park \& Young, 1986; Pignatiello, Camp, Raser, 1986) are all represented. Other researchers have used instrumental (Bailey, 1983; Eagle, 1971; Fried \& Berkowitz, 1979; Pignatiello, Camp \& Raser, 1986; Shatin, 1970; Riggs, 1937; Wheeler, 1985; Zalanowski, Stratton \& Campos, 1987) and vocal music (Bailey, 1983; Eagle, 1971; Henderson, 1983) in their work.

Various instrumentation has been explored. The guitar
(Bailey, 1983) and piano (Wheeler, 1985) appear as solo instruments, and arrangements for orchestras (Dowriey \& Knapp, 1927; Eagle, 1971; Fried \& Berkowitz, 1979; Pignatiello, Camp \& Raser, 1986; Riggs, 1937; Shatin, 1970; Zalanowski, Stratton \& Campos, 1987) vocals, (Shatin, 1970) and jazz bands (Fried \& Berkowitz, 1979) are implemented in other studies. Both style and instrumentation have been used in experiments but have not been scientifically examined.

Suggestion and Music
Suggestion can be defined as the acceptance of an idea without involving critical thought. Suggestion is a powerful tool and can be direct or indirect. A direct suggestion refers to explicit directives, such as when a professional has hypnotized a client. An indirect suggestion is a subtle form of influence, i.e., a professional recommending a treatment. Most often, the second definition is used and preferred (Chertok, 1986).

Suggestibility is influenced by a desire to conform to the wishes of authority figures (Ceci, Ross \& Toglia, 1987). Park and Young (1986) look to see if background music (popular) can suggest certain attitudes about products. In this study, music was a catalyst to the subjects' imagination and facilitated identification of certain images. Harkins and Petty (1987) used non-musical suggestion in their research. It was discovered that multiple sources significantly influence suggestion only
wher the subjects were not permitted to discuss their perceptions with their peers.

Programme music ("musical suggestion") can be defined as a narration or description that precedes a piece of music. Descriptions often originate from music historians, record album jackets, and on sheet music. This concept was introduced by the composer Franz Liszt and is a technique used by many composers. The idea of programme music is to focus attention on the poetic ideas of the music. By suggesting particular emotions in the preface of a composition, the music can indirectly represent feelings (Sadie, 1985).

Some claim that affective reactions are easily identified in compositions that can be characterized as programme music. Unpleasant emotions, such as despair and grief, are more frequently found than pleasant feelings, such as joy (Hampton, 1945). In a study by Riggs (1937), participants could distinguish sadness from joy, but progressively finer discriminations were not obtained. Measurement of Mood Responses

Historically, researchers have relied on verbal reports to record mood responses from subjects. Three basic methods used in collecting mood are: adjective check lists, semantic differences, and various types of rating scales, i.e., likert scale (Eagle, 1971).

Researchers have most frequently employed authorcompiled adjective check lists (Fried \& Berkowita, 1979;

Henderson, 1983; Larson, 1987; Riggs, 1937; Velter, 1968), the Depression Adjective Check List (DACL) (Leight \& Ellis 1981; Pignatiello et al., 1986; Rodrigue, Olson \& Markely, 1987), the Wessman \& Ricks (1966) Elation v. Depression Scale (Eagle, 1971; Wheeler, 1985), the Eight-State Questionnaire (Boyle, 1987), the Beck Depression Inventory (Pignatiello, Camp \& Raser, 1986), and the Profile of Mood States (POMS) (Bailey, 1983, Boyle, 1987) in their studies. Physiological measures have also been employed effectively in mood research. In a study by Ridgeway \& Waters (1987), the use of electromyography allowed the experimenter to monitor each subject's physiological response.

## Statement of the Problem

Music has been closely associated with mood in various studies. However, most of these studies have been descriptive in nature, with few employing systematic observation. This study implements a standardized mood assessment tool, the Profile of Mood States (McNair, Lorr \& Droppleman, 1981). Due to the lack of experimental research in this area, and the scarcity of studies specifically related to suggestion and music, further examination seems warranted. The purpose of this study is to examine the effects of verbal suggestion and music listening on mood perceptions.

Null Hypotheses
The null and alternative hypotheses for this study are as follows:

Ho There will be no difference in the subjects' mood states amorig the groups presented with suggestion and without suggestion prior to listening to music.

H1 There will be a difference in the subjects' mood states among the groups presented with suggestion and without suggestion prior to listening to music.

Ho There will be no difference in the subjects' mood states within each condition.

H1 There will be a difference in the subjects' mood states within each condition.

## Method

## Subjects

One hundred thirty-five undergraduate students enrolled at the Oniversity of the Pacific in Stockton, California participated in this study. Each group of volunteers was randomly assigned to one three conditions:

Condition $1=$ somber description and music (Massenet's "Meditation")

Condition $2=$ pleasant description and music (Massenet's "Meditation").

Condition $3=$ music alone
(Massenet's "Meditation")

## Design

A pretest was administered to each subject within each experimental condition. Subjects in Condition 1 were given a somber description followed with music listening.

Subjects in Condition 2 were given a pleasant description and listened to the same music. Those subjects in Condition 3 listened to the same music without a description. A posttest was given to all groups, and each subject completed a music questionnaire.

| 01 | X 1 | 02 |
| :---: | :---: | :---: |
| 01 | X 2 | 02 |
| 01 | X 3 | 02 |

## Experimental Variables

Dependent variables used for pre/post assessment of mood were the Profile of Mood States (POMS) and a music questionnaire (McNair, Lorr \& Droppleman, 1981; Appendix A). The POMS assessed an adults mood. Sixty-five items measured six dimensions of affect: Tension-Anxiety, Depression-Dejection, Anger-Hostility, Vigor-Activity, Fatigue-Inertia, and Confusion-Bewilderment. The testretest reliability for the six mood factors on the POMS ranged from .61-. 69, based on a study of 150 VA outpatients following four weeks of medical treatment. These figures are considerably lower than the figures associated with personality and intelligence, characteristics where testretest reliability is closer to $.80-.90$. Mood naturally fluctuates. Even with similar testing procedures some individuals exhibit wider mood swings than others and at different rates in time (MoNair, Lorr, Droppleman, 1981). For these reasons, test-retest reliability figures will normally be lower. Within the six mood scales, the internal
consistencies range from .84-. 95 .
Validity studies using the POMS have detected mood changes with psychotherapy, controlled outpatient drug trails and emotion-inducing conditions. Over an eight-week psychiatric treatment period, the means of 180 VA outpatients improved significantly (p<.001) within TensionAnxiety, Depression-Dejection, Anger-Hostility, and Fatigue (Lorr, McNair, Weinstein, Michaux \& Raskin, 1961). The POMS successfully identified changes associated with mild tranquilizers. In a comparison of two groups, chlordiazepoxide and a placebo, the group with the active drug displayed a greater reduction in Tension-Anxiety and a significant increase in Vigor, both of which occurred after one week of treatment (Lorr, McNair \& Weinstein, 1964).

Pillard and Fisher (1967) assessed the mood of 122 subjects before, during, and after viewing an anxietyinducing autopsy film. Subjects were given the POMS with either chlordiazepoxide, secobarbital, or a placebo after viewing a neutral film. Tension scores decreased from baseline scores following the neutral film, increased after the autopsy film, and decreased by the end of the experiment.

Concurrent validity coefficients comparing the POMS and the Hopkins Symptom Distress Scales range from .51-. 86 in all six affect categories. The POMS has also been correlated with other scales, yielding the following concurrent validity coefficients: Tension [Manifest Anxiety
( $x=.80, p<.01$ )], Depression [Inpatient Multidimensional Fsychiatric Scale ( $\underline{x}=30$, $p<.01$ )], Anger [Interpersonal Behavior Inventory Hostility ( $x=.32, p<.01$ )] and Vigor [Observer Rating of Interview Activity ( $\underline{r}=.29, \underline{p}<.05$ )].

An author devised Music Questionnaire (Appendix B) was completed after the posttest. This questionnaire had the subjects evaluate their feelings concerning the music and verbal descriptions, and requested pertinent demographic information.

Independent variables included verbal suggestion and slow tempo music. In two experimental conditions, a somber or pleasant verbal description was followed by music specifically selected to reinforce the description (Capurso, 1952).

Massenet's "Meditation" from the opera "Thais" applied to the somber and pleasant verbal descriptions. The music contained a long sweeping melody, soft dynamics and expressive phrases.

## Experimental Setting

The experiment was administered in the Wendell Phillips Center auditorium, room 140. This large room was capable of holding 45 people comfortably, and was equipped with cushioned chairs with removable desk tops. All chairs faced a platform where the experimenter stood. Fabric and thin wooden panels lined the walls and provided a sound proof environment. The subjects were tested in groups of 3-15 and sat in the first seven rows of the auditorium. All
directions and experimental conditions (music) were prerecorded and orally presented to the subjects.

Apparatus/Materials
A Magnavox Cassette Recorder, model number D8027/17L, was used to play the cassette tape. Each subject was supplied with a pencil and an assessment packet which contained a pretest, post-test and a music questionnaire.

## Procedures

Each subject was asked to sign a volunteer consent form (Appendix C) and refrain from talking before entering the testing area. Once the subjects had been seated, these directions were given:
"This experiment deals with music listening. You will be asked to complete a questionnaire at the beginning and end of the experiment. Take out the first questionnaire (white form). When you have finished, place the questionnaire under your chair and wait for the next step. Begin working on the first questionnaire now."

At the completion of the questionnaire, the following directions were given, based on the corresponding experimental conditions.

## Condition 1

"For the next four minutes you will listen to a piece of music that depicts the defense of personal honor. The year is 1789. The sun is setting slowly behind a stately manor. In a beautiful garden a duel has taken place and the young man has been injured defending his honor. His best friend was a witness to the event and stays with the wounded man until his death. Close your eyes and concentrate on the music. When the music stops, I will have you complete the second questionnaire. When you are finished, you may leave. '

## Condition 2

"For the next four minutes you will listen to a piece of music that depicts a rosy sun setting over a meadow. In
the flowery meadow lies a patch of soft grass just right for resting. Life is good and exciting. The meadow is inviting, re-vitalizing. Close your eyes and concentrate on the music. When the music stops, I will have you complete the second questionnaire. Wher you are finished, you may leave."

Condition 3
"For the next four minutes you will listen to a piece of music. Close your eyes and concentrate on the music When the music stops, I will have you complete the second questionnaire. Wheri you are finished, you may leave."

## Results

Pretest and posttest POMS mean scores (see Table 1) within conditions were compared using t-test analyses. The following significant comparisons were found: Mean scores for Condition 1 were 62.62 pretest and 54.24 posttest ( $\mathrm{df}=44, \mathrm{t}=2.05, \mathrm{p}<.05$ ); Condition 2 mean scores were 49.67 pretest and 41.53 posttest (df=44, $t=3.37, p<.05$ ); and Condition 3 showed mean scores of 48.44 pretest and 40.51 posttest ( $\underline{d f}=44, t=3.46, \underline{2}\langle .05)$. A significant affective state score between pre and posttest (see Table 2) was revealed within each of the three conditions for TensionAnxiety (p<.0001). Other statistically significant differences between pre and posttest measures were found on all affective states for Condition 3. Condition 2 showed significant differences on all affective states except Confusion and Vigor, with Condition 1 showing significant differences only on Tension-Anxiety and Vigor. The null hypothesis of no difference in the subjects mood state within each condition was rejected.

A one-way analysis of variance was used to analyze the

mean pretest POMS scores among the three conditions. A significant difference was found among the groups (see Table 3), thereby rejecting the assumption of homogeneity. An analysis of variance also revealed significant differences among the conditions on posttest scores (see Table 4).

The ratio of male to female was $69: 66$, and men and women were evenly distributed among the conditions. Data from the music questionnaire provided the researcher with subjects' opinions concerning the music and procedures used in the experimental process, such as 1) their preference for that music (see Table 5), 2) the frequency of experiencing images while listening to music (Table 6), and 3) their opinion concerning whether the depiction complemented the music (Table 7). Of the 135 tested, 37 recognized the music, but only one subject correctly identified the piece. A majority of the subjects (80\%) reported a preference for the musical selection used in the study with $30 \%$ stating that they "strongly liked" and $50 \%$ stating that they "liked the particular piece.

Of the 135 subjects tested, 31 (22\%) always, 56 (41\%) frequently, 38 ( $28 \%$ ) occasionally, 6 ( $4 \%$ ) seldom, and 4 ( $3 \%$ ) never experienced images while listening to music. Thirtytwo ( $71 \%$ ) of the 45 subjects in Condition 1 and $36(80 \%)$ of the 45 subjects in Condition 2 stated that the music complemented the verbal depiction.

Discussion
This study examined the effects of verbal suggestion
and music listening on mood changes of college students. Overall the subjects' mood-state altered, decreasing from pretest to posttest. A significant change did occur in all three experimental conditions as indicated by t-test analyses. In all conditions the music was consistent and may have enhanced mood changes.

The Tersion-Anxiety affective state was the only category to reach statistical difference in all three conditions. Similar results were obtained by Logan (1984), who found significant differences in the tension levels of subjects who listened to music. Exploring tension and anxiety is a current trend among researchers in music therapy and other related fields (Hanser, 1986). It is hoped that future studies will continue to examine the influence of music on such stress related disorders as hypertension, skin disorders, and respiratory ailments.

Condition 1 was given a somber description before listening to music. Post-test scores revealed that there was an increase in Depression, though not significant. This trend would seem to be "normal" since the subjects were asked to reflect on the death of a man. Interestingly, Vigor increased in Condition 1, as well as in 2 and 3. The experimental process lasted approximately twenty minutes, during which, each subject was passive. Numerous subjects reported that they were tired before entering the testing area but felt rested at the conclusion. Affect scores seem to reflect this state, since significant differences were
found for Vigor in Conditions 2 and 3.
Subjects in Condition 2 were given a pleasant description before listening to music. The verbal depiction and musical characteristics permitted the subjects to significantly decrease their scores in Depression, Anger, and Fatigue. It may be expected that when an individual is given the opportunity to reflect about a quiet, relaxing place, anxious and tense feelings may subside.

The analysis of variance failed to yield homogeneity among the three conditions. Without similar pretest scores, thorough analyses were not possible, making comparisons and conclusions of the posttest scores inappropriate. With a larger sample size or matched groups among the experimental conditions, a homogeneous population might have been obtained. It is suggested that future studies in this particular area consider sample size when conducting research.

Many subjects reported to have recognized the music used in the experiment. When asked to name the piece and composer, responses such as "Rhapsody in Blue" by Gershwin, the "Swan" by. Saint Saens, and Copland's "Appalachian Spring" were recorded. Only one subject correctly identified the piece of music. The majority of the subjects ( $80 \%$ ) "strongly liked" or "liked" the musical selection.

Most subjects reported that the verbal descriptions complemented the music (see Table 7). Since the same music was used with both depictions, these results are
ercouraging. It may be possible for the same piece of music to represent pleasant as well as somber ideas, depending upon prior suggestion. The selection, "Meditation" by Massenet is in a major mode. A soft and slow expressive melody was performed by a solo instrument and supported by an unobtrusive accompaniment. These findings are similar to those of Park and Young (1986) involving suggestion and music listening. In both studies, music was used to suggest images and ideas. Ninety-one percent of the subjects reported to have previously experienced images while listening to music, and the majority of the subjects found the music pleasing. From these particular results, it may be concluded that the music did enhance the depictions.

Music therapists frequently attempt to change the affective states of clients, e.g., to reduce tension and anxiety. A therapist may have a client listen to music with floating melodies to experience relaxation, or listen to a selection with strong rhythms to experience excitement. By placing a depiction with the music it could be possible for a therapist to guide a client to new or untouched emotions.

Based on the results of this project, future studies involving mood and music may examine 1) the length of the depiction, employing more detailed descriptions, 2) subjectderived depictions, and 3) various types of music which may enhance the descriptions. A longer verbal section would require the subjects to focus on the suggestion for a longer period of time. Additional information may be gained when
subjects are allowed to devise their own depiction and select preferred musical recordings to enhance mood change. Mood is a constantly fluctuating aspect of the human condition. It can vary from excitement to depression, from efficiency to confusion, and friendiness to spitefulness. Understanding how mood is effected by sensory stimulation, such as music, could possibly assist in the treatment of stress reduction and affective disorders. Only future research can provide adequate answers that may directly influence actual clinical practice.

## VOLUNTEER PARTICIPATION FORM

I, $\qquad$ volunteer to participate
in this research project on $\qquad$ , 1988. I understand that I will listen to some music and fill out two questionnaires.

Additionally, I will:

1) refrain from talking upon entering the room,
2) answer the questionnaires truthfully and to the best of my ability, and

3 ) understand that my name will not be requested on the questionnaires.

## Vita

The author was born and raised in California. In Fresno, she attended elementary and secondary schools and was involved in music activities. She participated in honor bands and orchestras and was a member of the Fresno Junior Philharmonic. As a high school senior she was involved in a primary mental health program, being a "Special Friend" for two young children.

In September, 1982 the author entered the misic therapy program at the University of the Pacific and graduated four years later with a Bachelor of Music in music therapy. While at UOP she was involved in the choral programs, a member of Mu Phi Epsilon (professional music fraternity), and a sweetheart for a social fraternity.

The author enjoyed performing, in addition to presenting a senior flute recital, she has played in student recital classes and church. In 1985, the Miss America Pageant awarded her a scholarship after her appearance in their program.

The author has worked with a wide variety of people. During a six-month internship at St Joseph's Medical Center in Stockton, Miss Cole worked with pediatrics, psychiatric adults, gero-psychiatrics, geriatric rehabilitation, and substance abusers.

In January, 1987, the author was awarded a teaching
assistantship in the music therapy department of UOP. She has enjoyed her involvement with the department and particularly the role of program coordinator of the Community Music Therapy Project, which provided free music lessons to handicapped children.

Currently the author is completing the course work for her master degree and is employed by the Central Methodist Church, Stockton, as the Director of Youth Ministries.
